- Conversion Time  $\leq 10 \mu\text{s}$
- 10-Bit-Resolution ADC
- Programmable Power-Down Mode . . .  $1 \mu\text{A}$
- Wide Range Single-Supply Operation of 2.7 V dc to 5.5 V dc
- Analog Input Range of 0 V to  $V_{CC}$
- Built-in Analog Multiplexer with 8 Analog Input Channels
- TMS320 DSP and Microprocessor SPI and QSPI Compatible Serial Interfaces
- End-of-Conversion (EOC) Flag
- Inherent Sample-and-Hold Function
- Built-In Self-Test Modes
- Programmable Power and Conversion Rate
- Asynchronous Start of Conversion for Extended Sampling
- Hardware I/O Clock Phase Adjust Input

## description

The TLV1544 and TLV1548 are CMOS 10-bit switched-capacitor successive-approximation (SAR) analog-to-digital (A/D) converters. Each device has a chip select ( $\overline{CS}$ ), input-output clock (I/O CLK), data input (DATA IN) and serial data output (DATA OUT) that provide a direct 4-wire synchronous serial peripheral interface (SPI™, QSPI™) port of a host microprocessor. When interfacing with a TMS320 DSP, an additional frame sync signal (FS) indicates the start of a serial data frame. The devices allow high-speed data transfers from the host. The  $\overline{INV CLK}$  input provides further timing flexibility for the serial interface.

In addition to a high-speed converter and versatile control capability, the device has an on-chip 11-channel multiplexer that can select any one of eight analog inputs or any one of three internal self-test voltages. The sample-and-hold function is automatic except for the extended sampling cycle, where the sampling cycle is started by the falling edge of asynchronous  $\overline{CSTART}$ . At the end of the A/D conversion, the end-of-conversion (EOC) output goes high to indicate that the conversion is complete. The TLV1544 and TLV1548 are designed to operate with a wide range of supply voltages with very low power consumption. The power saving feature is further enhanced with a software-programmed power-down mode and conversion rate. The converter incorporated in the device features differential high-impedance reference inputs that facilitate ratiometric conversion, scaling, and isolation of analog circuitry from logic and supply noise. A switched-capacitor design allows low-error conversion over the full operating temperature range.

## description (continued)

The TLV1544 has four analog input channels while the TLV1548 has eight analog input channels. The TLV1544C and TLV1548C are characterized for operation from 0°C to 70°C. The TLV1544I and TLV1548I are characterized for operation over the full industrial temperature range of -40°C to 85°C. The TLV1548M is characterized for operation over the full military temperature range of -55°C to 125°C.

**Terminal Functions**

TERMINAL			I/O	DESCRIPTION
NAME	NO.†	NO.‡		
A0–A3 A4–A7	6–9 –	1–4 5–8	I	Analog inputs. The analog inputs are internally multiplexed. (For a source impedance greater than 1 k $\Omega$ , the asynchronous start should be used to increase the sampling time.)
$\overline{CS}$	16	15	I	Chip select. A high-to-low transition on $\overline{CS}$ resets the internal counters and controls and enables DATA IN, DATA OUT, and I/O CLK within the maximum setup time. A low-to-high transition disables DATA IN, DATA OUT, and I/O CLK within the setup time.
$\overline{CSTART}$	10	9	I	Sampling/conversion start control. $\overline{CSTART}$ controls the start of the sampling of an analog input from a selected multiplex channel. A high-to-low transition starts the sampling of the analog input signal. A low-to-high transition puts the sample-and-hold function in hold mode and starts the conversion. $\overline{CSTART}$ is independent from I/O CLK and works when $\overline{CS}$ is high. The low $\overline{CSTART}$ duration controls the duration of the sampling cycle for the switched capacitor array. $\overline{CSTART}$ is tied to $V_{CC}$ if not used.
DATA IN	2	17	I	Serial data input. The 4-bit serial data selects the desired analog input and test voltage to be converted next in a normal cycle. These bits can also set the conversion rate and enable the power-down mode. When operating in the microprocessor mode, the input data is presented MSB first and is shifted in on the first four rising ( $\overline{INV CLK} = V_{CC}$ ) or falling ( $\overline{INV CLK} = GND$ ) edges of I/O CLK (after $\overline{CS}\downarrow$ ). When operating in the DSP mode, the input data is presented MSB first and is shifted in on the first four falling ( $\overline{INV CLK} = V_{CC}$ ) or rising ( $\overline{INV CLK} = GND$ ) edges of I/O CLK (after $FS\downarrow$ ). After the four input data bits have been read into the input data register, DATA IN is ignored for the remainder of the current conversion period.
DATA OUT	1	16	O	Three-state serial output of the A/D conversion result. DATA OUT is in the high-impedance state when $\overline{CS}$ is high and active when $\overline{CS}$ is low or after $FS\downarrow$ (in DSP mode). With a valid $\overline{CS}$ signal, DATA OUT is removed from the high-impedance state and is driven to the logic level corresponding to the MSB or LSB value of the previous conversion result. DATA OUT changes on the falling (microprocessor mode) or rising (DSP mode) edge of I/O CLK.
EOC	4	19	O	End of conversion. EOC goes from a high to a low logic level on the tenth rising (microprocessor mode) or tenth falling (DSP mode) edge of I/O CLK and remains low until the conversion is complete and data is ready for transfer. EOC can also indicate that the converter is busy.
FS	13	12	I	DSP frame synchronization input. FS indicates the start of a serial data frame into or out of the device. FS is tied to $V_{CC}$ when interfacing the device with a microprocessor.
GND	11	10		Ground return for internal circuitry. All voltage measurements are with respect to GND, unless otherwise noted.
$\overline{INV CLK}$	12	11	I	Inverted clock input. $\overline{INV CLK}$ is tied to GND when an inverted I/O CLK is used as the source of the input clock. This affects both microprocessor and DSP interfaces. $\overline{INV CLK}$ is tied to $V_{CC}$ if I/O CLK is not inverted. $\overline{INV CLK}$ can also invoke a built-in test mode.

### detailed description

Initially, with  $\overline{\text{CS}}$  high (inactive), DATA IN and I/O CLK are disabled and DATA OUT is in the high-impedance state. When the serial interface takes  $\overline{\text{CS}}$  low (active), the conversion sequence begins with the enabling of I/O CLK and DATA IN and the removal of DATA OUT from the high-impedance state. The host then provides the 4-bit channel address to DATA IN and the I/O clock sequence to I/O CLK. During this transfer, the host serial interface also receives the previous conversion result from DATA OUT. I/O CLK receives an input sequence from the host that is from 10 to 16 clocks long. The first four valid I/O CLK cycles load the input data register with the 4-bit input data on DATA IN that selects the desired analog channel. The next six clock cycles provide the control timing for sampling the analog input. Sampling of the analog input is held after the first valid I/O CLK sequence of ten clocks. The tenth clock edge also takes EOC low and begins the conversion. The exact locations of the I/O clock edges depend on the mode of operation.

### serial interface

The TLV1548 is compatible with generic microprocessor serial interfaces such as SPI and QSPI, and a TMS320 DSP serial interface. The internal latched flag  $\text{If\_mode}$  is generated by sampling the state of FS at the falling edge of  $\overline{\text{CS}}$ .  $\text{If\_mode}$  is set to one (for microprocessor) when FS is high at the falling edge of  $\overline{\text{CS}}$ , and  $\text{If\_mode}$  is cleared to zero (for DSP) when FS is low at the falling edge of  $\overline{\text{CS}}$ . This flag controls the multiplexing of I/O CLK and the state machine reset function. FS is pulled high when interfacing with a microprocessor.

## I/O CLK

The I/O CLK can go up to 10 MHz for most of the voltage range when fast I/O is possible. The maximum I/O CLK is limited to 2.8 MHz for a supply voltage range from 2.7 V. Table 1 lists the maximum I/O CLK frequencies for all different supply voltage ranges. This also depends on input source impedance. For example, I/O CLK speed faster than 2.39 MHz is achievable if the input source impedance is less than 1 k $\Omega$ .

Table 1. Maximum I/O CLK Frequency

V <sub>CC</sub>	MAXIMUM INPUT RESISTANCE (Max)	SOURCE IMPEDANCE	I/O CLK
2.7 V	5 K	1 k $\Omega$	2.39 MHz
		100 $\Omega$	2.81 MHz
4.5 V	1 K	1 k $\Omega$	7.18 MHz
		100 $\Omega$	10 MHz

## microprocessor serial interface

Input data bits from DATA IN are clocked in on the first four rising edges of the I/O CLK sequence if  $\overline{\text{INV CLK}}$  is held high when the device is in microprocessor interface mode. Input data bits are clocked in on the first four falling edges of the I/O CLK sequence if  $\overline{\text{INV CLK}}$  is held low. The MSB of the previous conversion appears on DATA OUT on the falling edge of  $\overline{\text{CS}}$ . The remaining nine bits are shifted out on the next nine edges (depending on the state of  $\overline{\text{INV CLK}}$ ) of I/O CLK. Ten bits of data are transmitted to the host through DATA OUT.

A minimum of 9.5 clock pulses is required for the conversion to begin. On the tenth clock rising edge, the EOC output goes low and returns to the high logic level when the conversion is complete; then the result can be read by the host. On the tenth clock falling edge, the internal logic takes DATA OUT low to ensure that the remaining bit values are zero if the I/O CLK transfer is more than ten clocks long.

$\overline{\text{CS}}$  is inactive (high) between serial I/O CLK transfers. Each transfer takes at least ten I/O CLK cycles. The falling edge of  $\overline{\text{CS}}$  begins the sequence by removing DATA OUT from the high-impedance state. The rising edge of  $\overline{\text{CS}}$  ends the sequence by returning DATA OUT to the high-impedance state within the specified delay time. Also, the rising edge of  $\overline{\text{CS}}$  disables I/O CLK and DATA IN within a setup time. A conversion does not begin until the tenth I/O CLK rising edge.

A high-to-low transition on  $\overline{\text{CS}}$  within the specified time during an ongoing cycle aborts the cycle, and the device returns to the initial state (the output data register holds the previous conversion result).  $\overline{\text{CS}}$  should not be taken low close to completion of conversion because the output data can be corrupted.

SLAS139C – DECEMBER 1996 – REVISED JANUARY 1999

## DSP interface

The TLV1544/1548 can also interface with a DSP, from the TMS320 family for example, through a serial port. The analog-to-digital converter (ADC) serves as a slave device where the DSP supplies FS and the serial I/O CLK. Transmit and receive operations are concurrent. The falling edge of FS must occur no later than seven I/O CLK periods after the falling edge of  $\overline{CS}$ .

DSP I/O cycles differ from microprocessor I/O cycles in the following ways:

- When interfaced with a DSP, the output data MSB is available after FS $\downarrow$ . The remaining output data changes on the rising edge of I/O CLK. The input data is sampled on the first four falling edges of I/O CLK after FS $\downarrow$  and when  $\overline{INV CLK}$  is high, or the first four rising edges of I/O CLK after FS $\downarrow$  and when  $\overline{INV CLK}$  is low. This operation is inverted when interfaced with a microprocessor.
- A new DSP I/O cycle is started on the rising edge of I/O CLK after the rising edge of FS. The internal state machine is reset on each falling edge of I/O CLK when FS is high. This operation is opposite when interfaced with a microprocessor.
- The TLV1544/1548 supports a 16-clock cycle when interfaced with a DSP. The output data is padded with six trailing zeros when it is operated in DSP mode.

**Table 2. TLV1544/TLV1548 Serial Interface Modes**

I/O	INTERFACE MODE	
	MICROPROCESSOR ACTION	DSP ACTION
$\overline{CS}\downarrow$	Initializes counter	Samples state of FS
$\overline{CS}\uparrow$	Resets state machine and disable I/O	Disables I/O
FS	Connects to $V_{CC}$	Connects to DSP FSX output Initializes the state machine at each CLK $\downarrow$ after FS $\uparrow$ Starts a new cycle at each CLK $\uparrow$ following the initialization (initializes the counter)
I/O CLK	Starts sampling of the analog input started at fourth I/O CLK $\uparrow$ Conversion started at tenth I/O CLK $\uparrow$	Starts sampling of the analog input at fourth I/O CLK $\downarrow$ Starts sampling of the analog input at tenth I/O CLK $\downarrow$
DATA IN	Samples input data on I/O CLK $\uparrow$ ( $\overline{INV CLK}$ high) Samples input data on I/O CLK $\downarrow$ ( $\overline{INV CLK}$ low)	Samples input data at I/O CLK $\downarrow$ ( $\overline{INV CLK}$ high) Samples input data at I/O CLK $\uparrow$ ( $\overline{INV CLK}$ low)
DATA OUT	Makes MSB available on $\overline{CS}\downarrow$ Changes remaining data on I/O CLK $\downarrow$	Makes MSB available FS $\downarrow$ Changes remaining data at each following I/O CLK $\uparrow$ after FS $\downarrow$

SLAS139C – DECEMBER 1996 – REVISED JANUARY 1999

**input data bits**

DATA IN is internally connected to a 4-bit serial input data register. The input data selects a different mode or selects different analog input channels. The host provides the data word with the MSB first. Each data bit clocks in on the edge (rising or falling depending on the status of  $\overline{\text{INV CLK}}$  and FS) of the I/O CLK sequence. The input clock can be inverted by grounding  $\overline{\text{INV CLK}}$  (see Table 3 for the list of software programmed operations set by the input data).

**Table 3. TLV1544/1548 Software-Programmed Operation Modes**

Reserved	1111b	Fh	No conversion result

**analog inputs and internal test voltages**

The eight analog inputs and the three internal test inputs are selected by the 11-channel multiplexer according to the input data bit as shown in Table 3. The input multiplexer is a break-before-make type to reduce input-to-input noise injection resulting from channel switching.

The device can be operated in two distinct sampling modes: normal sampling mode (fixed sampling time) and extended sampling mode (flexible sampling time). When  $\overline{\text{CSTART}}$  is held high, the device is operated in normal sampling mode. When operated in normal sampling mode, sampling of the analog input starts on the rising edge of the fourth I/O CLK pulse in the microprocessor interface mode (and on the fourth falling edge of I/O CLK in the DSP interface mode). Sampling continues for 6 I/O CLK periods. The sample is held on the falling edge of the tenth I/O CLK pulse in the microprocessor interface mode. The sample is held on the falling edge of the tenth I/O CLK pulse in the DSP interface mode. The three test inputs are applied to the multiplexer, then sampled and converted in the same manner as the external analog inputs.

## converter

The CMOS threshold detector in the successive-approximation conversion system determines the value of each bit by examining the charge on a series of binary-weighted capacitors (see Figure 1). In the first phase of the conversion process, the analog input is sampled by closing the  $S_C$  switch and all  $S_T$  switches simultaneously. This action charges all of the capacitors to the input voltage.

In the next phase of the conversion process, all  $S_T$  and  $S_C$  switches are opened and the threshold detector begins identifying bits by identifying the charge (voltage) on each capacitor relative to the reference (REF -) voltage. In the switching sequence, ten capacitors are examined separately until all ten bits are identified and then the charge-convert sequence is repeated. In the first step of the conversion phase, the threshold detector looks at the first capacitor (weight = 512). Node 512 of this capacitor is switched to the REF+ voltage, and the equivalent nodes of all the other capacitors on the ladder are switched to REF -. If the voltage at the summing node is greater than the trip point of the threshold detector (approximately one-half  $V_{CC}$ ), a bit 0 is placed in the output register and the 512-weight capacitor is switched to REF -. If the voltage at the summing node is less than the trip point of the threshold detector, a bit 1 is placed in the register and the 512-weight capacitor remains connected to REF + through the remainder of the successive-approximation process. The process is repeated for the 256-weight capacitor, the 128-weight capacitor, and so forth down the line until all bits are counted.

With each step of the successive-approximation process, the initial charge is redistributed among the capacitors. The conversion process relies on charge redistribution to count and weigh the bits from MSB to LSB.

Figure 1. Simplified Model of the Successive-Approximation System

SLAS139C – DECEMBER 1996 – REVISED JANUARY 1999

**extended sampling, asynchronous start of sampling:  $\overline{\text{CSTART}}$  operation**

The extended sampling mode of operation programs the acquisition time ( $t_{\text{ACQ}}$ ) of the sample-and-hold circuit. This allows the analog inputs of the device to be directly interfaced to a wide range of input source impedances. The extended sampling mode consumes higher power depending on the duration of the sampling period chosen.

$\overline{\text{CSTART}}$  controls the sampling period and starts the conversion. The falling edge of  $\overline{\text{CSTART}}$  initiates the sampling period of a preset channel. The low time of  $\overline{\text{CSTART}}$  controls the acquisition time of the input sample-and-hold circuit. The sample is held on the rising edge of  $\overline{\text{CSTART}}$ . Asserting  $\overline{\text{CSTART}}$  causes the converter to perform a new sample of the signal on the preset valid MUX channel (one of the eight) and discard the current conversion result ready for output. Sampling continues as long as  $\overline{\text{CSTART}}$  is active (negative). The rising edge of  $\overline{\text{CSTART}}$  ends the sampling cycle. The conversion cycle starts two internal system clocks after the rising edge of  $\overline{\text{CSTART}}$ .

Once the conversion is complete, the processor can initiate a normal I/O cycle to read the conversion result and set the MUX address for the next conversion. Since the internal flag AsyncFlag is set high, this flag setting indicates the cycle is an output cycle, so no conversion is performed during the cycle. The internal state machine tests the AsyncFlag on the falling edge of  $\overline{\text{CS}}$ . AsyncFlag is set high at the rising edge of  $\overline{\text{CSTART}}$ , and it is reset low at the rising edge of each  $\overline{\text{CS}}$ . A conversion cycle follows a sampling cycle only if AsyncFlag is tested as low at the falling edge of  $\overline{\text{CS}}$ . As shown in Figure 2, an asynchronous I/O cycle can be removed by two consecutive normal I/O cycles.

**Table 4. TLV1544/1548 Hardware Configuration for Different Operating Modes**

OPERATING MODES	$\overline{\text{CS}}$	$\overline{\text{CSTART}}$	AsyncFlag at $\overline{\text{CS}}\downarrow$	ACTION
Normal sampling	Low	High	Low	Fixed 6 I/O CLK sampling, synchronous conversion follows
Normal I/O (read out only)	Low	High	High	No sampling, no conversion
Extended sampling	High	Low	N/A	Flexible sampling period controlled by $\overline{\text{CSTART}}$ , asynchronous conversion follows

SLAS139C – DECEMBER 1996 – REVISED JANUARY 1999

- NOTES: A. Aa = Address for input channel a.  
 B. Da = Conversion result from channel a.

**Figure 2. Extended Sampling Operation**

**reference voltage inputs**

There are two reference inputs used with the TLV1544/TLV1548, REF+ and REF-. These voltage values establish the upper and lower limits of the analog inputs to produce a full-scale and zero-scale reading respectively. The values of REF+, REF-, and the analog input should not exceed the positive supply or be lower than GND consistent with the specified absolute maximum ratings. The digital output is at full scale when the input signal is equal to or higher than REF+ and is at zero when the input signal is equal to or lower than REF-.

**programmable conversion rate**

The TLV1544/TLV1548 offers two conversion rates to maximize battery life when high-speed operation is not necessary. The conversion rate is programmable. Once the conversion rate has been selected, it takes effect immediately in the same cycle and stays at the same rate until the other rate is chosen. The conversion rate should be set at power up. Activation and deactivation of the power-down state (digital logic active) has no effect on the preset conversion rate.

SLAS139C – DECEMBER 1996 – REVISED JANUARY 1999

**Table 5. Conversion Rate and Power Consumption Selection**

CONVERSION RATE	CONVERSION TIME, $t_{conv}$	AVAILABLE $V_{CC}$ RANGE	INPUT DATA	TYPICAL SUPPLY CURRENT, $I_{CC}$		
				OPERATING		POWER DOWN
Fast conversion speed	7 $\mu$ s typ	5.5 V to 3.3 V	9h	0.6 mA typ	1.5 mA max	1 $\mu$ A typ
Slow conversion speed	15 $\mu$ s typ	5.5 V to 2.7 V	Ah	0.4 mA typ	1 mA max	1 $\mu$ A typ

**programmable power-down state**

The device is put into the power-down state by writing 8h to DATA IN. The power-up state is restored during the next active access by pulling  $\overline{CS}$  low. The conversion rate selected before the device is put into the power-down state is not affected by the power-down mode. Power-down can be used to achieve even lower power consumption. This is because the sustaining power (when not converting) is only 1.3 mA maximum and standby power is only 1  $\mu$ A maximum. (By averaging out the power consumption can be much lower than the 1 mA peak when the conversion throughput is lower.)

**Figure 3. Typical Supply Current During Conversion/Power Down**

**power up and initialization**

After power up, if operating in DSP mode,  $\overline{CS}$  and FS must be taken from high to low to begin an I/O cycle. EOC is initially high, and the input data register is set to all zeroes. The content of the output data register is random, and the first conversion result should be ignored. For initialization during operation,  $\overline{CS}$  is taken high and returned low to begin the next I/O cycle. The first conversion after the device has returned from the power-down state can be invalid and should be disregarded.

When power is first applied to the device, the conversion rate must be programmed, and the internal Async Flag must be taken low once. The rising edge of  $\overline{CS}$  of the same cycle then takes Async Flag low.

**WITH SERIAL CONTROL AND 4/8 ANALOG INPUTS**

SLAS139C – DECEMBER 1996 – REVISED JANUARY 1999

**Figure 4. Power Up Initialization**

**input clock inversion –  $\overline{INV CLK}$**

The input data register uses I/O CLK as the source of the sampling clock. This clock can be inverted to provide more setup time.  $\overline{INV CLK}$  can invert the clock. When  $\overline{INV CLK}$  is grounded, the input clock for the input data register is inverted. This allows an additional one-half I/O CLK period for the input data setup time. This is useful for some serial interfaces. When the input sampling clock is inverted, the output data changes at the same time that the input data is sampled.

**Table 6. Function of  $\overline{INV CLK}$**

CONDITION CLOCK		I/O CLK ACTIVE EDGE	
$\overline{INV CLK}$	FS at $\overline{CS} \downarrow$	OUTPUT DATA CHANGES ON	INPUT DATA SAMPLED ON
High	High (MP <sup>†</sup> mode)	↓	↑
High	Low (DSP <sup>‡</sup> mode)	↑	↓
Low	High (MP <sup>†</sup> mode)	↓	↓
Low	Low (DSP <sup>‡</sup> mode)	↑	↑

<sup>†</sup> MP = microprocessor mode

<sup>‡</sup> DSP = digital signal processor mode

- NOTES: 2. Analog input voltages greater than the voltage applied to REF+ convert as all ones (1111111111), while input voltages less than the voltage applied to REF- convert as all zeros (0000000000). The device is functional with reference ( $V_{ref+} - V_{ref-}$ ) down to 1 V; however, the electrical specifications are no longer applicable.
3. To minimize errors caused by noise at  $\overline{CS}\downarrow$ , the internal circuitry waits for a setup time after  $\overline{CS}\downarrow$  before responding to control input signals. No attempt should be made to clock in an input dat until the minimum  $\overline{CS}$  setup time has elapsed.
4. This is the time required for the I/O CLK signal to fall from  $V_{IHmax}$  to  $V_{ILmin}$  or to rise from  $V_{ILmax}$  to  $V_{IHmin}$ . In the vicinity of normal room temperature, the devices function with an input clock transition time as slow as 1  $\mu\text{s}$  for remote data-acquisition applications where the sensor and the A/D converter are placed several feet away from the controlling microprocessor.

**APPLICATION INFORMATION**

- NOTES: A. This curve is based on the assumption that  $V_{ref+}$  and  $V_{ref-}$  have been adjusted so that the voltage at the transition from digital 0 to 1 ( $V_{ZT}$ ) is 0.0024 V, and the transition to full scale ( $V_{FT}$ ) is 4.908 V. 1 LSB = 4.8 mV.  
 B. The full-scale value ( $V_{FS}$ ) is the step whose nominal midstep value has the highest absolute value. The zero-scale value ( $V_{ZS}$ ) is the step whose nominal midstep value equals zero.

SLAS139C – DECEMBER 1996 – REVISED JANUARY 1999

---

**APPLICATIONS INFORMATION**

**simplified analog input analysis**

Using the equivalent circuit in Figure 33, the time required to charge the analog input capacitance from 0 to  $V_S$  within 1/2 LSB can be derived as follows:

The capacitance charging voltage is given by:

$$V_C = V_S \left( 1 - e^{-t_c / R_t C_i} \right)$$

where (1)

$$R_t = R_s + r_i$$

$$t_c = \text{Cycle time}$$

The input impedance  $Z_i$  is 1 k $\Omega$  at 5 V, and is higher (~ 5 k $\Omega$ ) at 2.7 V. The final voltage to 1/2 LSB is given by:

$$V_C (1/2 \text{ LSB}) = V_S - (V_S / 2048)$$
 (2)

Equating equation 1 to equation 2 and solving for cycle time  $t_c$  gives:

$$V_S - (V_S / 2048) = V_S \left( 1 - e^{-t_c / R_t C_i} \right)$$
 (3)

and time to change to 1/2 LSB (minimum sampling time) is:

$$t_{ch} (1/2 \text{ LSB}) = R_t \times C_i \times \ln(2048)$$

where

$$\ln(2048) = 7.625$$

Therefore, with the values given, the time for the analog input signal to settle is:

$$t_{ch} (1/2 \text{ LSB}) = (R_s + 1 \text{ k}\Omega) \times 55 \text{ pF} \times \ln(2048)$$
 (4)

This time must be less than the converter sample time shown in the timing diagrams. Which is 6x I/O CLK.

$$t_{ch} (1/2 \text{ LSB}) \leq 6 \times 1/f_{I/O}$$
 (5)

Therefore the maximum I/O CLK frequency is:

$$\max(f_{I/O}) = 6 / t_{ch} (1/2 \text{ LSB}) = 6 / (\ln(2048) \times R_t \times C_i)$$
 (6)

APPLICATIONS INFORMATION

† Driving source requirements:

- Noise and distortion for the source must be equivalent to the resolution of the converter.
- $R_S$  must be real at the input frequency.

Figure 40. Equivalent Input Circuit Including the Driving Source

maximum conversion throughput

For a supply voltage at 5 V, if the source impedance is less than 1 kΩ, this equates to a minimum sampling time  $t_{ch}$  (0.5 LSB) of 0.84 μs. Since the sampling time requires six I/O clocks, the fastest I/O clock frequency is  $6/t_{ch} = 7.18$  MHz. The minimal total cycle time is given as:

$$\begin{aligned} t_c &= t_{address} + t_{sample} + t_{conv} + t_d(EOC\uparrow - CS\downarrow) \\ &= 0.56 \mu s + 0.84 \mu s + 10 \mu s + 0.1 \mu s \\ &= 11.5 \mu s \end{aligned}$$

A maximum throughput of 87 KSPS. The throughput can be even higher with a smaller source impedance.

When source impedance is 100Ω, the minimum sampling time is 0.46 μs. The maximum I/O clock frequency possible is almost 13 MHz. Then 10 MHz clock (maximum I/O CLK for TLV1544/1548) can be used. The minimal total cycle time is:

$$\begin{aligned} t_c &= t_{address} + t_{sample} + t_{conv} + t_d(EOC\uparrow - CS\downarrow) \\ &= 4 \times 1/f + 0.46 \mu s + 10 \mu s + 0.1 \mu s \\ &= 0.4 \mu s + 0.46 \mu s + 10 \mu s + 0.1 \mu s \\ &= 10.96 \mu s \end{aligned}$$

The maximum throughput is  $1/10.96 \mu s = 91$  KSPS for this case.

(1) The marketing status values are defined as follows:

**ACTIVE:** Product device recommended for new designs.

**LIFEBUY:** TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

**NRND:** Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

**PREVIEW:** Device has been announced but is not in production. Samples may or may not be available.

**OBSOLETE:** TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

**RoHS Exempt:** TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

**Green:** TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of  $\leq 1000$ ppm threshold. Antimony trioxide based flame retardants must also meet the  $\leq 1000$ ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

**Important Information and Disclaimer:** The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.
